BIND(2)

Linux Programmer's Manual

BIND(2)

NAME top

bind - bind a name to a socket

SYNOPSIS top

DESCRIPTION top

When a socket is created with socket(2), it exists in a name space (address family) but has no address assigned to it. **bind**() assigns the address specified by addr to the socket referred to by the file descriptor sockfd. addrlen specifies the size, in bytes, of the address structure pointed to by addr. Traditionally, this operation is called "assigning a name to a socket".

It is normally necessary to assign a local address using bind()
before a SOCK STREAM socket may receive connections (see accept(2)).

The rules used in name binding vary between address families. Consult the manual entries in Section 7 for detailed information. For AF_INET , see ip(7); for AF_INET6 , see ipv6(7); for AF_UNIX , see packet(7); for AF_X25 , see x25(7); and for $AF_NETLINK$, see netlink(7).

The actual structure passed for the *addr* argument will depend on the

address family. The sockaddr structure is defined as something like:

struct sockaddr {
 sa_family_t sa_family;
 char sa_data[14];
}

The only purpose of this structure is to cast the structure pointer passed in addr in order to avoid compiler warnings. See EXAMPLE below.

RETURN VALUE top

On success, zero is returned. On error, -1 is returned, and *errno* is set appropriately.

ERRORS top

EACCES The address is protected, and the user is not the superuser.

EADDRINUSE

The given address is already in use.

EADDRINUSE

(Internet domain sockets) The port number was specified as zero in the socket address structure, but, upon attempting to bind to an ephemeral port, it was determined that all port numbers in the ephemeral port range are currently in use. See the discussion of /proc/sys/net/ipv4/ip_local_port_range ip(7).

EBADF sockfd is not a valid file descriptor.

EINVAL The socket is already bound to an address.

EINVAL addrlen is wrong, or addr is not a valid address for this socket's domain.

ENOTSOCK

The file descriptor sockfd does not refer to a socket.

The following errors are specific to UNIX domain (AF UNIX) sockets:

EACCES Search permission is denied on a component of the path prefix.
 (See also path_resolution(7).)

EADDRNOTAVAIL

A nonexistent interface was requested or the requested address was not local.

EFAULT addr points outside the user's accessible address space.

ELOOP Too many symbolic links were encountered in resolving addr.

ENAMETOOLONG

addr is too long.

ENOENT A component in the directory prefix of the socket pathname does not exist.

ENOMEM Insufficient kernel memory was available.

ENOTDIR

A component of the path prefix is not a directory.

EROFS The socket inode would reside on a read-only filesystem.

CONFORMING TO top

```
POSIX.1-2001, POSIX.1-2008, SVr4, 4.4BSD (bind() first appeared in 4.2BSD).
```

NOTES top

POSIX.1 does not require the inclusion of <sys/types.h>, and this header file is not required on Linux. However, some historical (BSD) implementations required this header file, and portable applications are probably wise to include it.

For background on the socklen t type, see accept(2).

BUGS top

The transparent proxy options are not described.

EXAMPLE top

An example of the use of **bind**() with Internet domain sockets can be found in getaddrinfo(3).

The following example shows how to bind a stream socket in the UNIX (AF_UNIX) domain, and accept connections:

```
#include <sys/socket.h>
#include <svs/un.h>
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#define MY SOCK PATH "/somepath"
#define LISTEN BACKLOG 50
#define handle error(msg) \
    do { perror(msq); exit(EXIT FAILURE); } while (0)
int
main(int argc, char *argv[])
    int sfd, cfd;
    struct sockaddr un my addr, peer addr;
    socklen_t peer_addr_size;
    sfd = socket(AF UNIX, SOCK STREAM, 0);
    if (sfd == -1)
        handle error("socket");
```

```
memset(&my addr, 0, sizeof(struct sockaddr un));
                               /* Clear structure */
           my addr.sun family = AF UNIX;
           strncpy(my_addr.sun_path, MY_SOCK PATH,
                   sizeof(my addr.sun path) - 1);
           if (bind(sfd, (struct sockaddr *) &my addr,
                   sizeof(struct sockaddr un)) == -1)
               handle error("bind");
           if (listen(sfd, LISTEN BACKLOG) == -1)
               handle error("listen");
           /* Now we can accept incoming connections one
              at a time using accept(2) */
           peer_addr_size = sizeof(struct sockaddr un);
           cfd = accept(sfd, (struct sockaddr *) &peer addr,
                        &peer addr size);
           if (cfd == -1)
               handle error("accept");
           /* Code to deal with incoming connection(s)... */
           /* When no longer required, the socket pathname, MY SOCK PATH
              should be deleted using unlink(2) or remove(3) */
       }
